

1GHz, 4 x 1 Multiplexing Amplifier with Synchronous Controls

The ISL59444 is a single-output 4:1 MUX-amp. The MUX-amp has a fixed gain of 1 and a 1GHz bandwidth. The ISL59444 is ideal for professional video switching, HDTV, computer display routing, and other high performance applications.

The device contains logic inputs for channel selection (S0, S1), latch control signals (LE1, LE2), and a three-state output control (HIZ) for individual selection of MUX amps that share a common video output line. All logic inputs have pull-downs to ground and may be left floating.

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

Timing Diagram

Features

- 1GHz (-3dB) Bandwidth ($V_{OUT} = 200mV_{P-P}$)
- 220MHz (-3dB) Bandwidth ($V_{OUT} = 2V_{P-P}$)
- Slew Rate ($R_L = 500\Omega, V_{OUT} = 4V$)1515V/ μ s
- Slew Rate ($R_L = 500\Omega, V_{OUT} = 5V$)1155V/ μ s
- High Speed Three-State Output (HIZ)
- Pb-Free Plus Anneal Available (RoHS Compliant)

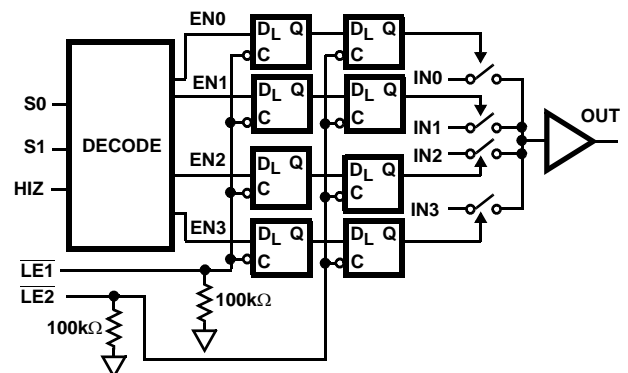

Applications

- HDTV/DTV Analog Inputs
- Video Projectors
- Computer Monitors
- Set-top Boxes
- Security Video
- Broadcast Video Equipment
- RGB Video Distribution Systems
- RF Switching and Routing

Pin Descriptions

PIN NUMBER	PIN NAME	EQUIVALENT CIRCUIT	DESCRIPTION
1	IN0	Circuit 1	Input for channel 0
2, 6, 8	NIC		Not Internally Connected; it is recommended this pin be tied to ground to minimize crosstalk.
3	IN1	Circuit 1	Input for channel 1
4	GND	Circuit 4	Ground pin
5	IN2	Circuit 1	Input for channel 2
7	IN3	Circuit 1	Input for channel 3
9	V -	Circuit 4	Negative Power Supply
10	$\overline{LE1}$	Circuit 2	Synchronized channel switching: When $\overline{LE1}$ is low, the master control latch loads the next switching address. The Mux Amp is configured for this address when $\overline{LE2}$ goes low. Synchronized operation results when $\overline{LE2}$ is the inverse of $\overline{LE1}$. Channel selection is asynchronous (changes with any control signal change) if both $\overline{LE1}$ and $\overline{LE2}$ are both low.
11	$\overline{LE2}$	Circuit 2	Synchronized channel switching: When $\overline{LE2}$ is low, the newly selected channel, stored in the master latch via $\overline{LE1}$ is selected. Synchronized operation results when $\overline{LE2}$ is the inverse of $\overline{LE1}$. Channel selection is asynchronous (changes with any control signal change) if both $\overline{LE1}$ and $\overline{LE2}$ are both low.
12	OUT	Circuit 3	Output
13	HIZ	Circuit 2	Output disable (active high); there are internal pull-down resistors, so the device will be active with no connection; "HI" puts the output in high impedance state.
14	S1	Circuit 2	Channel selection pin MSB (binary logic code)
15	S0	Circuit 2	Channel selection pin LSB (binary logic code)
16	V+	Circuit 4	Positive power supply

Application Information

General

The ISL59444 is a 4:1 mux that is ideal as a matrix element in high performance switchers and routers. The ISL59444 is optimized to drive a 2pF in parallel with a 500Ω load. The capacitance can be split between the PCB capacitance and external load capacitance. Their low input capacitance and high input resistance provide excellent 50Ω or 75Ω terminations.

Capacitance at the Output

The output amplifier is optimized for capacitance to ground (C_L) directly on the output pin. Increased capacitance causes higher peaking with an increase in bandwidth. The optimum range for most applications is ~1.0pF to ~6pF. The optimum value can be achieved through a combination of PC board trace capacitance (C_T) and an external capacitor (C_{OUT}). A good method to maintain control over the output pin capacitance is to minimize the trace length (C_T) to the next component, and include a discrete surface mount capacitor (C_{OUT}) directly at the output pin.

For large signal applications where overshoot is important the circuit in Figure 22B should be used. The series resistor (R_S) and capacitor (C_L) form a low pass network that limits system bandwidth and reduces overshoot. The component values shown result in a typical pulse response shown in Figure 18.

Ground Connections

For the best isolation and crosstalk rejection, the GND pin and NIC pins must connect to the GND plane. The NIC pins are placed on both sides of the input pins. These pins are not internally connected to the die. It is recommended this pin be tied to ground to minimize crosstalk.

Control Signals

S0, S1, HIZ - These pins are, TTL/CMOS compatible control inputs. The S0, S1 pins select which one of the inputs connect to the output. The HIZ pin is used to three-state the output amplifiers. For control signal rise and fall times less than 10ns the use of termination resistors close to the part will minimize transients coupled to the output.

HIZ State

An internal pull-down resistor connected to the HIZ pin ensures the device will be active with no connection to the HIZ pin. The HIZ state is established within approximately 30ns by placing a logic high (>2V) on the HIZ pin. If the HIZ state is selected, the output is a high impedance 1.4MΩ. Use this state to control the logic when more than one mux shares a common output.

In the HIZ state the output is three-stated, and maintains its high Z even in the presence of high slew rates. The supply current during this state is basically the same as the active state.

Latch State

The latched control signals allow for synchronized channel switching. When $\overline{LE1}$ is low the master control latch loads the next switching address ($S0$, $S1$), while the closed (assuming $\overline{LE2}$ is the inverse of $\overline{LE1}$) slave control latch maintains the current state. $\overline{LE2}$ switching low closes the master latch (with previous assumption), loads the now open slave latch, and switches the crosspoint to the newly selected channel. Channel selection is asynchronous (changes with any control signal change) if both $\overline{LE1}$ and $\overline{LE2}$ are low.

Power-Up Considerations

The ESD protection circuits use internal diodes from all pins the $V+$ and $V-$ supplies. In addition, a dv/dt triggered clamp is connected between the $V+$ and $V-$ pins, as shown in the Equivalent Circuits 1 through 4 section of the Pin Description table. The dv/dt triggered clamp imposes a maximum supply turn-on slew rate of $1V/\mu s$. Damaging currents can flow for power supply rates-of-rise in excess of $1V/\mu s$, such as during hot plugging. Under these conditions, additional methods should be employed to ensure the rate of rise is not exceeded.

Consideration must be given to the order in which power is applied to the $V+$ and $V-$ pins, as well as analog and logic input pins. Schottky diodes (Motorola MBR0550T or equivalent) connected from $V+$ to ground and $V-$ to ground (Figure 23) will shunt damaging currents away from the internal $V+$ and $V-$ ESD diodes in the event that the $V+$ supply is applied to the device before the $V-$ supply.

If positive voltages are applied to the logic or analog video input pins before $V+$ is applied, current will flow through the internal ESD diodes to the $V+$ pin. The presence of large decoupling capacitors and the loading effect of other circuits connected to $V+$, can result in damaging currents through the ESD diodes and other active circuits within the device. Therefore, adequate current limiting on the digital and analog inputs is needed to prevent damage during the time the voltages on these inputs are more positive than $V+$.

Limiting the Output Current

No output short circuit current limit exists on these parts. All applications need to limit the output current to less than 50mA. Adequate thermal heat sinking of the parts is also required.

PC Board Layout

The frequency response of this circuit depends greatly on the care taken in designing the PC board. The following are recommendations to achieve optimum high frequency performance from your PC board.

- The use of low inductance components such as chip resistors and chip capacitors is strongly recommended.
- Minimize signal trace lengths. Trace inductance and capacitance can easily limit circuit performance. Avoid sharp corners, use rounded corners when possible. Vias in the signal lines add inductance at high frequency and should be avoided. PCB traces greater than 1" begin to exhibit transmission line characteristics with signal rise/fall times of 1ns or less. High frequency performance may be degraded for traces greater than one inch, unless strip lines are used.
- Match channel-channel analog I/O trace lengths and layout symmetry. This will minimize propagation delay mismatches.
- Maximize use of AC de-coupled PCB layers. All signal I/O lines should be routed over continuous ground planes (i.e. no split planes or PCB gaps under these lines). Avoid vias in the signal I/O lines.
- Use proper value and location of termination resistors. Termination resistors should be as close to the device as possible.
- When testing use good quality connectors and cables, matching cable types and keeping cable lengths to a minimum.
- Minimum of 2 power supply de-coupling capacitors are recommended (1000pF, 0.01 μ F) as close to the devices as possible. Avoid vias between the cap and the device because vias add unwanted inductance. Larger caps can be farther away. When vias are required in a layout, they should be routed as far away from the device as possible.
- The NIC pins are placed on both sides of the input pins. These pins are not internally connected to the die. It is recommended these pins be tied to ground to minimize crosstalk.
