

DRAM

1 MEG x 4 DRAM

QUAD CAS PARITY, FAST PAGE MODE

DRAM

FEATURES

- Four independent $\overline{\text{CAS}}$ controls, allowing individual manipulation to each of the four data Input/Output ports (DQ1 through DQ4).
- Offers a single chip solution to byte level parity for 36-bit words when using 1 Meg x 4 DRAMs for memory
- Emulates write-per-bit, at design-in level, with simplified timing constraints
- High performance, CMOS silicon gate process
- Single +5V±10% power supply
- Low power, 3mW standby; 225mW active, typical
- All inputs, outputs and clocks are fully TTL and CMOS compatible
- 1024-cycle refresh in 16ms
- Refresh modes: $\overline{\text{RAS}}$ -ONLY, $\overline{\text{CAS}}$ -BEFORE- $\overline{\text{RAS}}$, and HIDDEN
- $\overline{\text{CAS}}$ -BEFORE- $\overline{\text{RAS}}$ cycles with $\overline{\text{WE}}$ as a don't care

GENERAL DESCRIPTION

The MT4C4004 is a randomly accessed solid-state memory containing 4,194,304 bits organized in a x4 configuration. This 1 Meg x 4 DRAM is unique in that each $\overline{\text{CAS}}$ ($\overline{\text{CAS1}}$ through $\overline{\text{CAS4}}$) controls its corresponding data I/O port in conjunction with $\overline{\text{OE}}$ (eg. $\overline{\text{CAS1}}$ controls DQ1 I/O port, $\overline{\text{CAS2}}$ controls DQ2, $\overline{\text{CAS3}}$ controls DQ3 and $\overline{\text{CAS4}}$ controls DQ4).

The best way to view the Quad $\overline{\text{CAS}}$ function is to imagine the $\overline{\text{CAS}}$ inputs going into an AND gate to obtain an internally generated $\overline{\text{CAS}}$ signal functioning in an identical manner to the single $\overline{\text{CAS}}$ input on a standard 1 Meg x 4 DRAM device. The key difference is each $\overline{\text{CAS}}$ controls its corresponding DQ tristate logic (in conjunction with $\overline{\text{OE}}$ and $\overline{\text{WE}}$) on the Quad CAS DRAM.

During READ or WRITE cycles, each bit is uniquely addressed through the 20 address bits, which are entered 10 bits (A0-A9) at a time. $\overline{\text{RAS}}$ is used to latch the first 10 bits,

PIN ASSIGNMENT (Top View)

24-Pin SOJ (E-5, E-6)

DQ1	1	28	V _{SS}
DQ2	2	25	DQ4
$\overline{\text{WE}}$	3	24	DQ3
$\overline{\text{RAS}}$	4	23	$\overline{\text{CAS4}}$
$\overline{\text{CAS1}}$	5	22	$\overline{\text{OE}}$
$\overline{\text{CAS2}}$	6	21	$\overline{\text{CAS3}}$
A9	8	19	NC
A0	9	18	A8
A1	10	17	A7
A2	11	16	A6
A3	12	15	A5
V _{CC}	13	14	A4

NC = Pin is a 'no connect'

and the first $\overline{\text{CAS}}$ the latter 10 bits. A READ or WRITE cycle is selected with the $\overline{\text{WE}}$ input. A logic HIGH on $\overline{\text{WE}}$ dictates READ mode while a logic LOW on $\overline{\text{WE}}$ dictates WRITE mode.

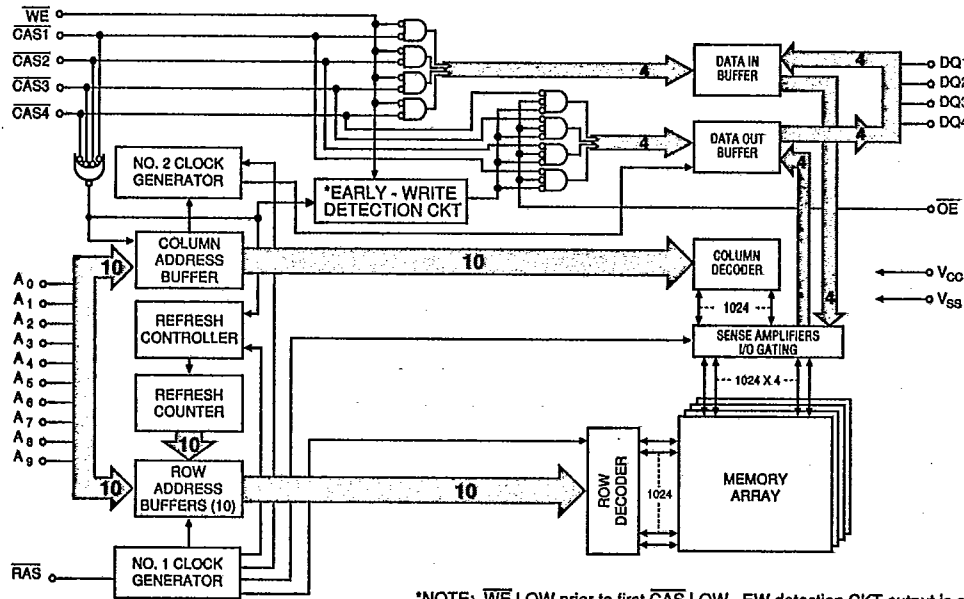

During a WRITE cycle, data-in (D_x) is latched by the falling edge of $\overline{\text{WE}}$ or the first $\overline{\text{CAS}}$, whichever occurs last. If $\overline{\text{WE}}$ goes LOW prior to the first $\overline{\text{CAS}}$ going LOW, the output pin(s) remain open (High-Z) until the next $\overline{\text{CAS}}$ cycle. If $\overline{\text{WE}}$ goes LOW after data reaches the output buffer, data out (Q) is activated and retains the selected cell data until the trailing edge of its corresponding $\overline{\text{CAS}}$ occurs (regardless of $\overline{\text{WE}}$ or $\overline{\text{RAS}}$). This late $\overline{\text{WE}}$ pulse results in a READ-WRITE cycle ($\overline{\text{OE}}$ switching the device from a READ to a WRITE function). The four data inputs and four data outputs are routed through four pins using common I/O, with pin direction controlled by $\overline{\text{WE}}$ and $\overline{\text{OE}}$.

FAST PAGE MODE operations allow faster data operations (READ, WRITE or READ-MODIFY-WRITE) within a row address (A0-A9) defined page boundary. The FAST PAGE MODE cycle is always initiated with a row address strobed-in by $\overline{\text{RAS}}$ followed by a column address strobed-in by the first $\overline{\text{CAS}}$. $\overline{\text{CAS}}$ may be toggled-in by holding $\overline{\text{RAS}}$ LOW and strobing-in different column addresses, thus executing faster memory cycles. Returning $\overline{\text{RAS}}$ HIGH terminates the FAST PAGE MODE operation.

Returning $\overline{\text{RAS}}$ and all four $\overline{\text{CAS}}$ controls HIGH terminates a memory cycle and decreases chip current to a reduced standby level. Also, the chip is preconditioned for the next cycle during the $\overline{\text{RAS}}$ high time. Memory cell data is retained in its correct state by maintaining power and executing any $\overline{\text{RAS}}$ cycle (READ, WRITE, $\overline{\text{RAS}}$ -ONLY, $\overline{\text{CAS}}$ -BEFORE- $\overline{\text{RAS}}$ or HIDDEN refresh) so that all 1024 combinations of $\overline{\text{RAS}}$ addresses (A0-A9) are executed at least every 16ms, regardless of sequence. The $\overline{\text{CAS}}$ -BEFORE- $\overline{\text{RAS}}$ cycle will invoke the refresh counter for automatic and sequential row addressing.

ABSOLUTE MAXIMUM RATINGS*

Voltage on Vcc supply relative to Vss -1.0V to +7.0V
 Storage Temperature (Ceramic) -65°C to +150°C
 Storage Temperature (Plastic) -55°C to +150°C
 Power Dissipation 1W
 Short Circuit Output Current 50mA

*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

NOTES

1. All voltages referenced to V_{SS} .
2. This parameter is sampled. Capacitance is calculated from the equation $C = I^{dt}/dv$ with $dv = 3V$ and $V_{CC} = 5V$.
3. I_{CC} is dependent on cycle rates.
4. I_{CC} is dependent on output loading and cycle rates. Specified values are obtained with minimum cycle time and the outputs open.
5. Enables on-chip refresh and address counters.
6. The minimum specifications are used only to indicate cycle time at which proper operation over the full temperature range is assured.
7. An initial 100 μ s pause is required after power-up followed by eight \overline{RAS} refresh cycles (\overline{RAS} -ONLY or CBR) before proper device operation is assured. The eight \overline{RAS} cycle wake-up should be repeated any time the 8ms refresh requirement is exceeded.
8. AC characteristics assume $t_T = 5ns$.
9. V_{IH} (MIN) and V_{IL} (MAX) are reference levels for measuring timing of input signals. Transition times are measured between V_{IH} and V_{IL} (or between V_{IL} and V_{IH}).
10. In addition to meeting the transition rate specification, all input signals must transit between V_{IH} and V_{IL} (or between V_{IL} and V_{IH}) in a monotonic manner.
11. If $\overline{CAS}_x = V_{IH}$, data output (Q_x) is high impedance.
12. If $\overline{CAS}_x = V_{IL}$, Q_x may contain data from the last valid READ cycle.
13. Measured with a load equivalent to 2 TTL gates and 100pF.
14. Assumes that $t_{RCD} < t_{RCD} (MAX)$. If t_{RCD} is greater than the maximum recommended value shown in this table, t_{RAC} will increase by the amount that t_{RCD} exceeds the value shown.
15. Assumes that $t_{RCD} \geq t_{RCD} (MAX)$.
16. If at least one \overline{CAS} is LOW at the falling edge of \overline{RAS} , Q will be maintained from the previous cycle. To initiate a new cycle and clear the Q buffer, all four \overline{CAS} controls must be pulsed HIGH for t_{CPN} .
17. Operation within the $t_{RCD} (MAX)$ limit ensures that $t_{RAC} (MAX)$ can be met. $t_{RCD} (MAX)$ is specified as a reference point only; if t_{RCD} is greater than the specified $t_{RCD} (MAX)$ limit, then access time is controlled exclusively by t_{CAC} .
18. Operation within the $t_{RAD} (MAX)$ limit ensures that $t_{RCD} (MAX)$ can be met. $t_{RAD} (MAX)$ is specified as a reference point only; if t_{RAD} is greater than the specified $t_{RAD} (max)$ limit, then access time is controlled exclusively by t_{AA} .
19. Either t_{RCH} or t_{RRH} must be satisfied for a READ cycle.
20. $t_{OFF} (MAX)$ defines the time at which the output achieves the open circuit condition and is not referenced to V_{OH} or V_{OL} .
21. t_{WCS} , t_{RWD} , t_{AWD} and t_{CWD} are restrictive operating parameters in EARLY-WRITE and READ-WRITE cycles only. If $t_{WCS} \geq t_{WCS} (min)$, the cycle is an EARLY-WRITE cycle and the data output will remain an open circuit throughout the entire cycle. If $t_{RWD} \geq t_{RWD} (MIN)$, $t_{AWD} \geq t_{AWD} (MIN)$ and $t_{CWD} \geq t_{CWD} (MIN)$, the cycle is a READ-WRITE cycle, and the data output will contain data read from the selected cell. If neither of the above conditions are met, the state of data out are indeterminate. \overline{OE} held HIGH and \overline{WE} taken LOW after \overline{CAS} goes LOW results in a LATE-WRITE (\overline{OE} controlled) cycle. (at access time and until \overline{CAS} or \overline{OE} goes back to V_{IH})
22. These parameters are referenced to \overline{CAS}_x leading edge in early WRITE cycles and \overline{WE} leading edge in late WRITE or READ-WRITE cycles.
23. If \overline{OE} is tied permanently LOW, READ-WRITE or READ-MODIFY-WRITE operations are not possible.
24. A HIDDEN REFRESH may also be performed after a WRITE cycle. In this case, $\overline{WE} = LOW$ and $\overline{OE} = HIGH$.
25. One to three \overline{CAS} controls may be HIGH throughout any given \overline{CAS} cycle, even though the timing waveforms show all \overline{CAS} controls going LOW. If any one does go LOW, it must meet all the timing requirements listed or the data for that I/O buffer may be invalid. At least one of the four \overline{CAS} controls must be LOW for a valid \overline{CAS} cycle to occur.
26. All other inputs at $V_{CC} - 0.2V$.
27. The first \overline{CAS}_x edge to transition LOW.
28. The last \overline{CAS}_x edge to transition HIGH.
29. Output parameter (DQ_x) is referenced to corresponding \overline{CAS}_x input; DQ_1 by \overline{CAS}_1 , DQ_2 by \overline{CAS}_2 , etc.
30. Last falling \overline{CAS}_x edge to first rising \overline{CAS}_x edge.
31. Last rising \overline{CAS}_x edge to next cycle's last rising \overline{CAS}_x edge.
32. Last rising \overline{CAS}_x edge to first falling \overline{CAS}_x edge.
33. First DQ_x controlled by the first \overline{CAS}_x to go LOW.
34. Last DQ_x controlled by the last \overline{CAS}_x to go HIGH.
35. Each \overline{CAS}_x must meet minimum pulse width.
36. Last \overline{CAS}_x to go LOW.
37. LATE-WRITE and READ-MODIFY-WRITE cycles must have both t_{OD} and t_{OEH} met (\overline{OE} HIGH during WRITE cycle) in order to ensure that the output buffers will be open during the WRITE cycle. The DQ_s will provide the previously read data if \overline{CAS} remains LOW and \overline{OE} is taken back LOW after t_{OEH} is met. If the last \overline{CAS}_x goes HIGH prior to \overline{OE} going back LOW, the DQ_s will remain open.
38. The DQ_s open during READ cycles once t_{OD} or t_{OFF} occur. If the last \overline{CAS}_x goes HIGH first, \overline{OE} becomes a don't care. If \overline{OE} goes HIGH and \overline{CAS}_x stays LOW, \overline{OE} is not a don't care; and the DQ_s will provide the previously read data if \overline{OE} is taken back LOW (while \overline{CAS}_x remains LOW).

QUAD CAS MODULE UPGRADE

The MT4C4004 (Quad CAS DRAM) was developed to supersede the 1 Meg DRAMs used in the current 1 Meg and 2 Meg x 36 DRAM modules and to add leading-edge CMOS performance. The MT4C4004 is a 1 Meg x 4 CMOS FAST-PAGE-MODE DRAM with four CAS input controls. The four individual CAS inputs allow each I/O buffer (DQ) to be separately controlled, just as if there were four separate 1 Meg x 1 DRAMs. Most 1 Meg x 1 DRAMs use older CMOS technology and do not have the access speeds of the newer CMOS 4 Meg (1 Meg x 4).

The MT4C4004 will reduce chip count on a x36 module; improving reliability, reducing power consumption and

lowering cost. The 1 Meg x 36 will have four 1 Meg x 1 DRAMs replaced by either one or two Quad CAS DRAMs, depending on whether RAS0 and RAS1 must be separate or can be connected together. The 2 Meg x 36 will have eight 1 Meg x 1 DRAMs replaced by either two or four Quad CAS DRAMs, depending on whether RAS0, RAS1, RAS2, and RAS3 must be split or can be connected together.

The current 1 Meg x 36 DRAM Module is shown with 256K x 1 DRAMs in Figure 1 below. Figures 2 and 3 show how the same module will be realized with the Quad CAS DRAM for both the split RAS (Figure 2) and the common RAS (Figure 3) modules.
