

# STV2000

# I2C SINGLE FREQUENCY DEFLECTION PROCESSOR AND 70 MHz RGB PREAMPLIFIER

#### PRELIMINARY DATA

### **FEATURES**

### **Horizontal deflection**

- Single frequency, self adaptive oscillator.
- TTL compatible positive going sync.
- I<sup>2</sup>C controlled: H-position, Pin Cushion, Keystone, Parallelogram, Side Pin Balance,Hamplitude.
- DC East/West feedback.
- DC controls: H-width breathing compensation.
- X-Ray protection

### Vertical deflection

- Vertical ramp generator.
- Wide range AGC loop.
- TTL compatible positive going sync, no extra pulses.
- I<sup>2</sup>C controls: vertical position and S-correction.
- DC controls: height breathing compensation.

### Video preamplifier

- 3-channel 70MHz bandwidth RGB preamplifier.
- 5ns typical rise and fall time at 4V<sub>PP</sub>.
- I<sup>2</sup>C controls: RGB contrast, cut-off, brightness, contrast up-date during vertical retrace time.
- ABL will reduce gain (contrast).
- 0.514V typical video input signal for normal display.

### I<sup>2</sup>C Main features

- I<sup>2</sup>C interface (slave) 100kHz max.
- All I<sup>2</sup>C controlled DAC are 7bit, except for RGB gain and cut-off.
- Power- on- reset at 5 V (V<sub>DD</sub>).
- 0.5 to 4 V static DAC output.

### Supply voltage & power

- 5 V/10.5 V dual supply.
- Max power consumption: 1.2W

### DESCRIPTION

The STV2000 is an I<sup>2</sup>C-controlled monolithic integrated circuit assembled in a TQFP44 plastic package. It combines both a deflection block (horizontal and vertical, single frequency with very powerful geometry correction) and a 70MHz RGB pre-amplifier.

### **PIN CONNECTIONS**

#### Version 3.0

April 2000

This is preliminary information on a new product involved and product in

### **OPERATING DESCRIPTION**

### **A SCANNING PART**

#### 1. GENERAL CONSIDERATIONS

#### 1.1 Power Supply

Typical power supply voltages are 10.5 V for the Deflection and Preamplifier sections (SAV<sub>CC</sub>, VAV<sub>CC</sub> and PV<sub>CC</sub>) and 5.0 V for the logic section (Vdd). Optimum operation is obtained between 9.5 and 11.5 for V<sub>CC</sub>, and between 4.5 and 5.5 V for V<sub>DD</sub>.

 $V_{CC}$  is monitored during the transient phase when switched either on or off, to avoid erratic operation of the circuit. If  $V_{CC}$  is inferior to 6.9 V typ., the circuit outputs are inhibited. Similarly, before  $V_{DD}$  reaches 4 V, all the I<sup>2</sup>C registers are reset to their default value (see I<sup>2</sup>C Control Table).

The circuit is internally supplied by several voltage references (typ. value: 8 V) to ensure a good power supply rejection. Two of these voltage references are externally accessible respectively for the vertical and horizontal parts. They can be used to bias external circuitry if  $I_{LOAD}$  is inferior to 5 mA. To minimize the noise and consequently the "jitter" on vertical and horizontal output signals, the reference voltages must be filtered by external capacitors connected to the ground.

#### **1.2 I<sup>2</sup>C Control**

STV2000 belongs to the I<sup>2</sup>C-controlled device family. Each adjustment can be made via the I<sup>2</sup>C Interface, instead of being controlled by DC voltages on dedicated control pins. The I<sup>2</sup>C bus is a serial bus with a clock and a data input. General function and bus protocol are specified in the Philips-bus data sheets. The interface (Data and Clock) is TTL-compatible. Spikes up to 50 ns are filtered by an integrator and the maximum clock speed is limited to 100 kHz.

The data line (SDA) can be used bidirectionally. In read mode, the IC sends reply information (1 byte) to the micro-processor.

The bus protocol prescribes a full-byte transmission in all cases. The first byte after the start condition is used to transmit the IC address (hexa 8C for write, 8D for read).

All bytes are sent MSB bit first and the write data transfer is closed by a stop.

#### 1.3 Write Mode

In write mode, the second byte contains the subaddress of the selected function to adjust (or controls to effect) and the third byte the corresponding data byte. More than one data byte can be sent to the IC. If after the third byte no stop or start condition is detected, the circuit automatically increments the momentary subaddress in the subaddress counter (auto-increment mode) by one. Thus it is possible to immediately transmit the following data bytes without sending the IC address or subaddress. This can be useful for reinitializing all the controls very quickly (flash manner). This procedure is ended with a stop condition.

There are 19 adjustment capabilities for the circuit: 3 for the horizontal part, 3 for the vertical, 3 for the E/W correction, 2 for the dynamic horizontal phase control, 7 for the preamplifier and 1 for the blanking DC. 14 bits are also dedicated to several controls (ON/OFF).

#### 1.4 Read Mode

In the read mode the second byte transmits the reply information. The reply byte contains the horizontal and vertical lock/unlock status, the XRAY activation status. A stop condition always stops all the activities of the bus decoder and switches both the data and clock line (SDA and SCL) to high impedance. See I<sup>2</sup>C subaddress and control tables.

#### 1.5 Sync Processor

The internal sync processor allows the device to receive separate horizontal & vertical TTL-compatible sync signals.

#### 1.6 IC Status

The IC informs the MCU about both the 1st horizontal PLL (locked or not) and the XRAY protection (activated or not). The XRAY internal latch is reset either directly via the  $I^2C$  interface or by decreasing the V<sub>CC</sub> supply.

#### **1.7 Sync Inputs**

Both HIN and VIN inputs are TTL compatible triggers with hysterisis to avoid erratic detection. Both inputs include a pull-up resistor connected to  $V_{DD}$ . Synchro pulses must be positive.

#### 1.8 Sync Processor Output

The sync processor indicates whether 1st PLL is locked to an incoming horizontal sync or not. This is indicated on the D8 bit of the status register . PLL1 level is low when locked.

### 2. HORIZONTAL PART

#### 2.1 Internal Input Conditions

A digital signal (horizontal sync pulse) is sent by the sync processor to the horizontal input. It must be positive (see Figure 4).

Synchronization occurs on the leading edge of the internal sync signal.

The minimum value of Z is 0.7  $\mu$ s.

Vertical synchro extraction is not allowed.

#### Figure 4.

### 2.2 PLL1

57

The PLL1 consists of a phase comparator, an external filter and a voltage-controlled oscillator (VCO). The phase comparator is a "phase frequency" type designed in CMOS technology. This kind of phase detector avoids locking on wrong

#### Figure 6. Block Diagram

frequencies. It is followed by a "charge pump", composed of two current sources: sunk and sourced (typically I =1 mA when locked and I = 140  $\mu$ A when unlocked). This difference between lock/unlock allows smooth catching of the horizontal frequency by PLL1. This effect is reinforced by an internal original slow down system when PLL1 is locked, preventing the horizontal frequency from changing too quickly. The dynamic behaviour of PLL1 is fixed by an external filter which integrates the current of the charge pump. A "CRC" filter is generally used (see Figure 5).

19/38

#### Figure 7. Details of VCO

The VCO uses an external RC network. It delivers a linear sawtooth resulting from the capacitor charge and discharge. The current is proportional to the one in the resistor. Typical thresholds for the sawtooth are 1.6 V and 6.4 V.

The VCO control voltage varies between 3.0 V and 3.8 V (see Figure 7). This VCO frequency range is very small. The small effective frequency is due to clamp intervention on the lowest filter value. The PLL1F filter voltage is set by a 4-bit DAC with a voltage range of 3.0 to 3.8 V.

The sync frequency must always be higher than the free running frequency. For example, when using a 60 kHz synchro range, the suggested free running frequency is 56 kHz. PLL1 ensures the coincidence between the leading edge of the sync signal and a phase reference resulting from the comparison of:

- the VCO sawtooth
- an internal DC voltage I2C adjustable within the range of 2.9V to 4.2V (corresponding to  $\pm 10\%$ ) (see Figure 8).

A Lock/Unlock identification block, also included, detects in real time whether PLL1 is locked on the incoming horizontal sync signal or not.

The lock/unlock information is available through the  ${\rm I}^2 C$  read.

The FC1 Pin (Pin 43) is used for decoupling the internal 6.4 V reference by a capacitor.

*[*5]

### Figure 8. PLL1 Timing Diagram

#### 2.3 PLL2

PLL2 ensures a constant position of the shaped flyback signal in comparison with the sawtooth of the VCO, taking into account the saturation time Ts (see Figure 9).

#### Figure 9. PLL2 Timing Diagram

The phase comparator of PLL2 (phase type comparator) is followed by a charge pump (typical output current: 0.5 mA).

The flyback input consists of an NPN transistor.

This input must be current driven. The maximum recommended input current is 5 mA (see Figure 10).

#### Figure 10. Flyback Input Electrical Diagram

The duty cycle is fixed at 48%. For a safe start-up operation, the initial duty cycle (after power-on reset) is 85% in order to avoid having too long a conduction period of the horizontal scanning transistor.

The maximum storage time (Ts Max.) is :

0.44T<sub>H</sub>- T<sub>FLY</sub>/2). Typically, T<sub>FLY</sub>/T<sub>H</sub> corresponds to around 20 % which means that Ts max represents approxim tively 34 % of T<sub>H</sub>.

#### 2.4 Output Section

The H-drive signal is sent to the output through a shaping stage which also controls the fixed Hdrive duty cycle (see Figure 9). In order to secure the scanning power part operation, the output is inhibited in the following cases :

-when V<sub>CC</sub> is too low,

-when the ABL protection is activated,

-during the Horizontal flyback,

-when the HDrive I<sup>2</sup>C bit control is off.

The output stage consists of a NPN bipolar transistor. Only the collector is accessible (see Figure 11).

#### Figure 11.

This output stage is intended for "reverse" base control, where setting the output NPN in off-state will control the power scanning transistor in offstate.

The maximum output current is 15 mA, and the corresponding voltage drop of the output V<sub>CEsat</sub> is 0.4 V Max.

Obviously, the power scanning transistor cannot be directly driven by the integrated circuit. An interface either bipolar or MOS type has to be added between the circuit and the power transistor.

#### 2.5 X-RAY Protection

X-Ray protection is activated when the ABL input (1 V on Pin 20) is at a low level. It inhibits both H-Drive, and Vout while Video goes into off-mode.

This activation is internally delayed by 2 lines to avoid erratic detection (short parasitics).

This protection is latched; it may be reset either by switching  $V_{CC}$  off or by  $I^2C$  (see Figure 12).

Figure 12. Safety Functions Block Diagram

### 3. VERTICAL PART

#### 3.1 Function

When the synchronization pulse is not present, an internal current source sets the free running frequency. For an external capacitor,  $C_{OSC} = 150$ nF, the typical free running frequency is 100Hz.

The typical free running frequency can be calculated according to:

ed according to: fo(Hz) =  $1.5 \cdot 10^{-5} \cdot \frac{1}{C_{OSC}}$ 

A positive TTL level pulse applied on Pin 1(Vin) is used to synchronize the ramp in the range [fmin, fmax] (see Figure 13). This frequency range depends on the external capacitor connected on Pin 5. A 150nF ( $\pm$  5%) capacitor is recommended for 50 Hz to 165 Hz applications.

The typical maximum and minimum frequency, at 25°C and without any correction (S correction),

can be calculated as follows:

 $f(Max.) = 3.5 \text{ x f}_0 \text{ and } f(Min.) = 0.33 \text{ x f}_0$ 

When an S correction is applied, these values are slightly modified.

With a synchronization pulse, the internal oscillator is synchonized immediately but its amplitude changes. An internal correction then adjusts it in less than half a second. The ramp top value (Pin 5) is sampled on the AGC capacitor (Pin 3) at each clock pulse. A transconductance amplifier modifies the charge current of the capacitor so as to make the amplitude constant again. We recommend using an AGC capacitor with a low leakage current. A value lower than 100nA is mandatory.

A good level of stability for the internal closed loop is obtained by a 470nF  $\pm\,5\%$  capacitor value on Pin 3 (VAGC).

VRB (Pin 8) is used for decoupling the internal 2V reference voltage by a capacitor.

### 3.2 I<sup>2</sup>C Control Adjustments

S correction shapes can then be added to this ramp. This frequency-independent S correction is generated internally. Its amplitudes is adjustable via the I<sup>2</sup>C. S correction can be inhibited by applying the selected bits.

Finally, the amplitude of the S corrected ramp is adjustable via the vertical ramp amplitude control register. The adjusted ramp is available on Pin 6 ( $V_{OUT}$ ) to drive an external power stage.

The gain of this stage can be adjusted ( $\pm 25\%$ ) depending on its register value.

The mean value of this ramp is driven by its own  $I^2C$  register (vertical position) with : VPOS = 7/16 x V<sub>REF-V</sub> = ± 300 mV.

Usually V<sub>OUT</sub> is sent through a resistive divider to the inverting input of the booster. Since VPOS derives from V<sub>REF-V</sub>, the bias voltage sent to the non-inverting input of the booster should also derive from V<sub>REF-V</sub> to optimize the accuracy (see Figure 13).

I

#### 3.3 Basic Equations

As a first approximation, the amplitude of the ramp on Pin 6 (VOUT) is calculated as follows:

 $V_{OUT}$  - VPOS =  $(V_{OSC}$  -  $V_{DCMID})$  x (1 + 0.25  $(V_{AMP}))$  where :

 $V_{DCMID} = 7/16 \times V_{REF}$  (middle value of the ramp on Pin 5, typically 3.6V)

 $V_{OSC} = V_5$  (ramp with fixed amplitude)

V<sub>AMP</sub> = -1 as minimum vertical amplitude register

value and +1 as maximum value.

VPOS is calculated according to:

 $VPOS = V_{DCMID} + (0.4x V_P)$ 

where  $V_P = -1$  and +1 as respectively minimum and maximum vertical position register value.

The current available on Pin 5 is:

$$OSC = \frac{5}{8} \times V_{REF} \times C_{OSC} \times f$$
  
where

 $C_{OSC}$  = capacitor connected on Pin 5 f = synchronization frequency.

### **3.4 Geometric Corrections**

The principle is represented in Figure 14.

Starting from the vertical ramp, a parabola-shaped current is generated for E/W correction (also known as Pin Cushion correction), dynamic horizontal phase control correction.

The parabola generator consists of an analog multiplier, the output current of which is equal to :

### $\Delta I = k x (V_{OUT} - V_{DCMID})^2$

where V<sub>OUT</sub> is the vertical output ramp (typically between 2 and 5 V) and V<sub>DCMID</sub> is 3.6 V (for V<sub>REF-V</sub> = 8.2V). The VOUT sawtooth is typical-

(for  $V_{REF-V} = 8.2V$ ). The VOUT sawtooth is typically centered on 3.6 V. By changing the vertical position, the sawtooth shifts by ±0.4 V.

The "geometry tracking" feature ensures a correct screen geometry for any end user adjustment. It generates non-symmetric parabola dependent on the vertical position.

Due to the large output stage voltage range (E/W Pin Cushion, Keystone), the combination of the tracking function, maximum vertical amplitude, maximum or minimum vertical position and maxi-

Figure 14. Geometric Corrections Principle

mum gain on the DAC control may lead to output stage saturation. This must be avoided by limiting the output voltage with appropriate  $l^2C$  register values. For the E/W part and the dynamic horizontal phase control part, a sawtooth-shaped differential current in the following form is generated:

 $\Delta I' = k' \cdot (V_{OUT} - V_{DCMID}).$ 

Then  $\Delta I$  and  $\Delta I'$  are added and converted into voltage for the E/W part.

Each of the two E/W components or the two dynamic horizontal phase control components may be inhibited by their own  $I^2C$  select bit.

Internal EW correction voltage is not available directly on the output pin. The EW correction is obtained with the feedback voltage (Pin 27: EWBin) which generates a modulating current in the diode (Pin 28). In addition, the horizontal width is I<sup>2</sup>Ccontrolled.

The dynamic horizontal phase control drives the H-position internally, moving the HFLY position on the horizontal sawtooth in the range of  $\pm 2.8 \ \% T_H$  both for side pin balance and parallelogram.

### 3.5 E/W

EWOUT = EW<sub>DC</sub> + K1 (V<sub>OUT</sub> - V<sub>DCMID</sub>) +K2 (V<sub>OUT</sub> - V<sub>DCMID</sub>)<sup>2</sup> K1 is adjustable via the keystone I<sup>2</sup>C register. K2 is adjustable via the E/W amplitude I<sup>2</sup>C register.

#### 3.6 Dynamic Horizontal Phase Control

 $I_{OUT}$ = K4 (V<sub>OUT</sub> - V<sub>DCMID</sub>) + K5 (V<sub>OUT</sub> - V<sub>DCMID</sub>)<sup>2</sup> K4 is adjustable via the parallelogram I<sup>2</sup>C register.

K5 is adjustable via the side pin balance  $I^2C$  register.

### 3.7 Horizontal Breathing

Horizontal breathing compensation is performed through the EW stage with the Voltage-Current Converter. This DC-controlled input provides the required horizontal width corrections to offset width changes arising from EHT variations.

### **B PRE-AMPLIFIER PART**

#### 1. GENERAL CONSIDERATIONS

#### 1.1 Input Stage

The R, G and B signals must be supplied to the three inputs through coupling capacitors (100nF). The maximum input peak-to-peak video amplitude is 1 V.

Figure 15. .

#### 3.8 Vertical Breathing

Vertical breathing compensation is performed through the gain modulation of the vertical ramp. This DC-controlled input provides the vertical height corrections required to offset height changes arising from EHT variations.

The input stage includes a clamping function. This clamp uses the input serial capacitor as "memory capacitor" and is gated by an internally generated "Back-Porch-Clamping-Pulse (BPCP)".

The BPCP is synchronized on the second edge of the horizontal pulse HIN inputs on Pin 44.

In both cases, BPCP width is fixed.

#### 1.2 Contrast Adjustment (7 bits)

The contrast adjustment is made by simultaneously controlling the gain of three internal variable gain amplifiers through the I<sup>2</sup>C bus interface. The contrast adjustment allows covering a range higher than 40 dB. This adjustment is refreshed during the vertical retrace time.

#### 1.3 ABL Control

The STV2000 has an ABL input (automatic beam limitation) to attenuate RGB video signals according to beam intensity.

The operating range is typically 2.5 V, from 5.3 V to 2.0 V. A typical 12 dB Max. attenuation is applied to the signal whatever the current gain. Refer to Figure 16 for ABL input attenuation range.

In the case of software control, the ABL input must be pulled to  ${\rm AV}_{\rm CC}$  through a resistor to limit power consumption.

ABL input voltage must not exceed VAV<sub>CC</sub>. Input resistor is  $10k\Omega$ .

#### Figure 16.

#### 1.4 Brightness Adjustment (6 bits)

As with contrast adjustment, brightness is controlled by  $\mathrm{I}^{2}\mathrm{C}.$ 

The brightness function consists of adding the same DC offset to the three R, G, B signals after contrast amplification. This DC-Offset is present only outside the blanking pulse (see Figure 18).

The DC output level is forced to "INFRA-BLACK" level ( $V_{DC}$ ) during the blanking pulse.

#### 1.5 Drive Adjustment (3 x 8 bits)

To adjust the white balance, the device offers the possibility of separately adjusting the overall gain of each complete video channel. Each channel gain is controlled by I<sup>2</sup>C (8 bits each). The very

#### Figure 17.

large drive adjustment range (48dB) allows different standard or custom color temperatures.

The drive adjustment is also used to adjust the output voltages at the optimum amplitude to drive the C.R.T drivers, keeping the whole contrast control for end-users only. The drive adjustment is made after the contrast and brightness so that the white balance remains correct when BRT is adjusted.

#### 1.6 Output Stage

The three output stages (see Figure 17) incorporate three functions:

- The blanking stage: when the internal generated blanking pulse is high, the three outputs are switched to a voltage which is 400 mV lower than the BLACK level. The black level is the output voltage with minimum brightness when the input signal video amplitude is equal to "0".
- The output stage itself: a large bandwidth output amplifier which can deliver up to 5V<sub>PP</sub> on the three outputs (for 0.7 V video signal on the inputs).
- The output CLAMP: the IC also incorporates three internal output clamps (sample and hold system) used for the DC to shift the three output signals. The DC output voltage is fixed at 1.5 V.

The overall waveforms of the output signal according to the different adjustments are shown in Figure 18.and Figure 19.

*[*5]

Figure 18. Waveforms VOUT, BRT, CONT

#### 1.7 Cutoff DAC Output

Three Cutoff DACs (8 bits) with output buffers are incorporated to drive the external cutoff circuit. Output voltage range is from 0.5 V to 4.5 V.

#### **1.8 Blanking Generator**

A vertical blanking pulse is generated (see Figure 20). The output level is a positive going pulse of 8V. The vertical blanking is started by the vertical sync pulse and the duration is determined by counting 22 horizontal periods. If there is no vertical sync pulse the vertical blanking start coincides with the beginning of the vertical capacitor discharge time.

The blanking output generates a superimposed variable DC voltage. The 6-bit adjustment range is 1 V to 4.5 V. This is used to allow brightness control through G1. Additionally, this pin is used for spot killer suppression. The  $0.8 \vee$  of Vcc threshold will trigger the output into a high level state resulting from the Vcc decay.

**/** 

### 1.9 DAC Output

This is a 7-bit DAC with 1 output pin. An output buffer is used to enhance load capability with an Imax(source) of 2 mA.

#### Table 1:Logic Table

| Conditions   | Hout   | Vout   | Video-off    | Low Power |
|--|--------|--------|--------------|-----------|
| V <sub>cc</sub> at 0 to 6.9 V (PD2 mode)               | no     | no     | video-off    | NA (1)    |
| V <sub>cc</sub> at 6.9 V to 8.5 V (PD1 mode)           | yes    | yes    | video-off    | NA(1)     |
| I <sup>2</sup> C DPMS bit=1, (default=0)               | no     | no     | video-off    | yes       |
| Hlock/unlock detection = unlock                        | yes    | yes    | video-off    | no        |
| Video ABL input pin < 1 V                              | no     | no     | video-off    | no        |
| 5 V POR or I <sup>2</sup> C POR=1, (default=0)         | yes    | yes    | video-off    | no        |
| I <sup>2</sup> C Hout on/off, (default=1=on)           | on/off | yes    | on/off       | no        |
| I <sup>2</sup> C Vout on/off, (default=1=on)           | yes    | on/off | on/off       | no        |
| I <sup>2</sup> C Video on/off, (default=0=video-off)   | yes    | yes    | on/off       | no        |
| V <sub>cc</sub> at >8.5 V                              | yes    | yes    | video-on (2) | NA (1)    |
| V <sub>cc</sub> at >8.5 V, I <sup>2</sup> C video=1=on | yes    | yes    | video-on (2) | no        |

Note 1 NA= Not applicable.

Note 2  $I^2C$  video=on will be reset by  $I^2CDPMS/Low V_{cc}$ .

### **C** STAND-BY MODE AND PROTECTIONS

#### 1. GENERAL CONSIDERATIONS

#### 1.1 POR (Power On Reset) - Subadress 11- D8

POR is activated on 5 V with default values for each adjustment and in addition video off (see 1.3). It can be activated via the  $I^2C$  command.

#### 1.2 Supply Voltage Threshold.

Two built-in thresholds (see figure 21) are used to enter the following modes:

- PDI mode:
  - Activated for Vcc < 8.5V</li>
  - Video off (see 1.13)
- PD2 mode:

57

- Activated for Vcc < 6.9V</li>
- Video off (see 1.13)
- $H_{OUT}$  and  $V_{OUT}$  disabled

### 1.3 Video Off (I<sup>2</sup>C control) - Subadress 00 - D8

Activates blanking of the 3 video output stages. During this time the outputs are switched to ground level, regardless of the presence of Hsync or Hflyback. Activation time is inferior to  $1\mu$ s.

This also activates the blanking output generating a positive going signal at pin 24 as long as "video off" is activated.

#### 1.4 Vertical Output Off

This command will switch off output VAMP. The vertical output swing is reduced to 0V. During power saver mode, the total vertical section is disabled.

#### 1.5 Power Saver On - Subadress 11 - D7

This I<sup>2</sup>C command activates the PD1 and PD2 mode regardless of the scanning Vcc value. Internal scanning and pre-amp voltage are off. During "power saver" mode, the device power consumption will be reduced to below 20mA for all supply pins. Vdd, I<sup>2</sup>C interface and DAC data are not affected by this command.

#### 1.6 X-Ray, Set Operation - Subadress 09 - D8

When ABL voltage is below 1 V threshold, Xray latch will be activated. This  $I^2C$  command will reset the Xray latch. Activation time below 100ms.
